Principles of AI Planning

Exercise Sheet 3

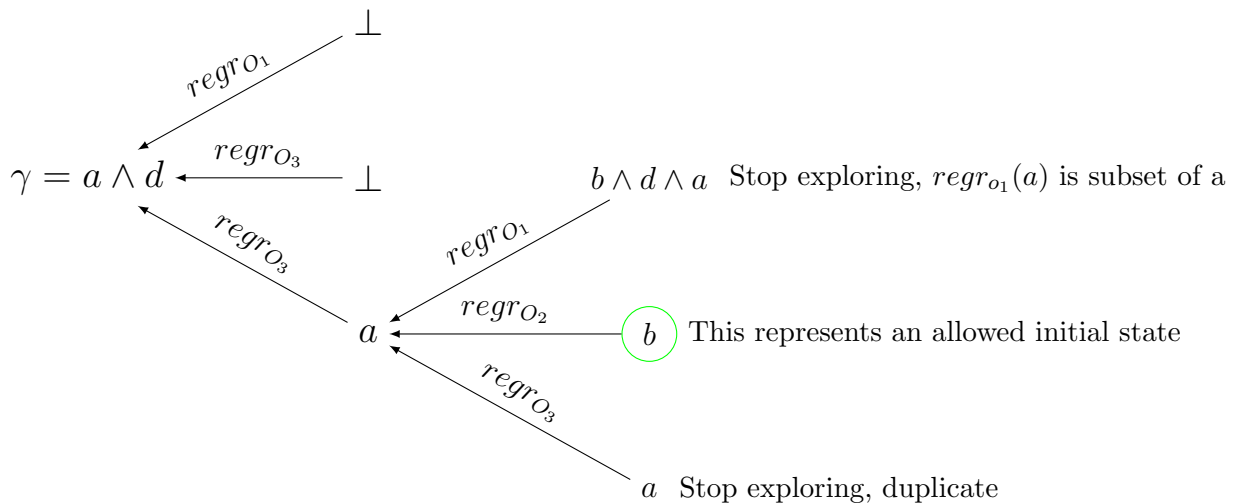

6.11.2019

Exercise 3.1: STRIPS Regression

a) Consider the STRIPS planning tasks with:

$$\begin{aligned}
 A &= \{a, b, c, d, e\} \\
 I &= \{a \mapsto 0, b \mapsto 1, c \mapsto 0, d \mapsto 1, e \mapsto 1\} \\
 \gamma &= a \wedge d \\
 O &= \{o_1, o_2, o_3\} \\
 o_1 &= \langle b \wedge d, c \wedge e \wedge \neg d \rangle \\
 o_2 &= \langle b, a \wedge \neg c \wedge \neg d \rangle \\
 o_3 &= \langle a, d \rangle
 \end{aligned}$$

Solve this problem with a breadth-first search using the STRIPS regression method.

Exercise 3.2: Problem modeling

The plan obtained by the custom planner with the PDDL program was the following:

```
(move g b)  
(sample-rock b r1)  
(move b c)  
(sample-rock c r2)  
(move c d)  
(sample-rock d r3)  
(move d e)  
(sample-rock e r4)  
(move e g)  
(move g f)  
(move f a)  
(transmit-data a r4)  
(transmit-data a r3)  
(transmit-data a r2)  
(transmit-data a r1)
```

We can notice the obtained plan with the custom planner is optimal as it satisfies the problem conditions with the least cost.
